

PYTHON ASSIGNMENT 2
[IMPLEMENT ANY 2 FROM FOLLOWING]

1. Write a single python program to do the following operations on a text file by writing different user defined functions.
 - a. Remove all the special characters.
 - b. Remove all single characters.
 - c. Substitute multiple spaces with single space.
 - d. Convert all the words into Lowercase.
 - e. Convert the words into literal form from their contracted form (e.g., Couldn't → Could not)
2. Implement one multi-threaded server with socket programming in python.
3. Implement one hospital information system using Python and any of the databases among MySQL, PostgreSQL, SQLite, MongoDB with following information –

- i) Connect to your database server and print its version.
 - ii) Fetch Hospital and Doctor Information using hospital Id and doctor Id.
 - iii) Get the list Of doctors as per the given specialty and salary.
 - iv) Get a list of doctors from a given hospital.
 - v) Update doctor experience in years.
4. Write a python program to build a term-document matrix $M_{m \times n}$ (occurrence of terms in a document) from a set of n text documents (n will be user given). The output will be a .csv file containing rows that represent unique terms and columns that represent documents.
5. Write a python script for implementing matrix factorization that represents a matrix in the product of matrices. The outputs of each of the following matrices will be stored in .csv files

$$M = U \Sigma V^T$$

Where,

M is an $m \times n$ matrix,

U : is the matrix of the eigenvectors of $M^T M$ and size of $m \times m$

Σ : is a diagonal matrix containing the singular values obtained as square roots of the eigenvalues of $M^T M$ and of size $m \times n$ | $k \times k$ where k will be user given. The values of the diagonal will be represented in decreasing order.

V : is the matrix of the eigenvectors of MM^T

V^T is the transpose of V .
